ABSTRACT

Veridex is a web-based, rule-driven public information reliability and verification system developed to address the growing challenge of misinformation in digital platforms. The system evaluates the reliability of publicly shared information using deterministic, predefined rules rather than artificial intelligence or subjective judgment. Users submit public information claims along with supporting sources, which are systematically analyzed to generate transparent reliability indicators without asserting absolute truth or authoritative validation.

The **main objectives of the Veridex system are**:

- To evaluate the reliability of publicly shared information using deterministic, rule-based logic
- To identify and highlight outdated or temporally irrelevant information
- To detect conflicting claims and inconsistencies within the system
- To improve public awareness and promote informed decision-making
- To reduce the impact and spread of misinformation through transparent verification

To ensure structured interaction and system integrity, Veridex defines multiple user roles. The **five primary actors involved in the system are**:

- **General User** – submits claims, views reliability indicators, and participates in anonymous discussions
- **Anonymous Community Participant** – engages in claim-specific discussions and polls without identity disclosure
- **Contributor** – adds or updates sources and provides clarifications for submitted claims
- **Moderator** – oversees claims and community activity and manages misuse or violations
- **Administrator** – configures system rules, manages user roles, and maintains overall system control

Implemented as a modular client–server web application, Veridex emphasizes transparency, explainability, user privacy, and auditability. By combining deterministic rule-based verification with controlled anonymous community engagement, the system supports responsible information consumption, strengthens digital trust, and provides a scalable framework suitable for academic evaluation and future institutional or research-oriented deployment.
